

A Short Summary of the Evaluate Modelling Language

William S. Page
Structural Analysis Division
Statistics Canada
January 2, 1987.

Introduction

Evaluate is a vector-oriented modelling language. It is based on the algebraic properties of the category of ordinary sets and set-functions. For more details on the design of the language see "Extended Vector Algebra Language EVALUATE", Structural Analysis Division Working paper, William S. Page, June 28, 1983.

This version of Evaluate is written in "C" and is implemented under Eunice (a UNIX shell for VMS) on a VAX 8600 and under the MSDOS operating system on a Compaq 286 micro-computer. It consists of two levels. The upper level handles the high-level language including variable definitions and scenario (variable value) management. High-level language statements are translated to low-level shell command sequences. These command sequences consist of a number of filters which implement the low-level Evaluate data manipulations. The following is a short summary of the Evaluate high-level language. A brief tutorial with examples will be available shortly.

Vectors are defined in terms of domains. Domains represent sets. In programming languages such as Pascal, domains would be referred to as data types.

A Short Summary of the Evaluate Modelling Language

A Short Summary of the Evaluate Modelling Language

1) Domain Constants

| <u>Name</u> | <u>Syntax</u> | <u>Description</u> |
|--------------|---------------|-------------------------------|
| real numbers | REAL | real (floating point) numbers |
| titles | TITLE | character strings |
| zero | 0 | empty set |
| unit | 1 | unnamed singleton set |

2) Domain Expressions

For any domains A B C etc.

| <u>Name</u> | <u>Syntax</u> | <u>Description</u> |
|--------------|--------------------|-------------------------------|
| pairing | (A,B,C ...) | cross-product, set of tuples |
| | (a:A,b:B,c:C ...) | labelled pairing |
| glueing | (A;B;C ...) | disjoint union |
| | (a:A;b:B;c:C ...) | labelled glueing |
| vector space | (A->B) | set of vectors |
| title set | {name} | subset (e.g. name:50->TITLE) |
| grouping set | [name] | partition (e.g. name:SIC->50) |
| enumeration | 2 | = (1;1) |
| etc. | 3 | = (1;1;1) etc. |

3) Elements

The elements of domain A belong to vector space (1->A):

4) Data types

A pairing is similar to the notion of a record data type in programming languages such as Pascal. A glueing is similar to a variant record data type. A vector space is similar to an array data type.

5) Vectors and arrays

Vectors are strongly-typed total functional mappings from a subject domain to an object domain. Vectors are a generalization of the notion of an array in programming languages such as Pascal. The subject and object of a vector are given by a notation called a signature:

name:subject->object

A Short Summary of the Evaluate Modelling Language

6) Signature

The signature of a vector defines the vector space to which the vector belongs. In Pascal this would correspond to the data type:

```
var name:array [subject] of object;
```

7) Matrix

A vector whose subject is a pairing and whose object is REAL, corresponds to the usual notion of a matrix. For example,

```
matrix:(row,column)->REAL
```

8) Time series

A time series is a vector whose subject is a time title set, i.e. a vector with signature $n \rightarrow \text{REAL}$ and whose object is REAL. For example, suppose

```
t81t90:10->REAL
```

is a vector containing 1981;1982; ... 1990, then

```
tpop:out{t81t90!}->REAL
```

*which has been evaluated
so out \t81t90.1*

might be a time series representing the total population from 1981 to 1990 in one year increments.

9) Vector constants

| <u>Examples</u> | <u>Signature</u> | <u>Description</u> |
|-----------------|------------------|--------------------|
| 3.141592 | 1->REAL | real number |
| "Iron Ore" | 1->TITLE | title |

9.1) Projections and Injections

For any domains A B etc., associated with the pairing or glueing of A and B, we have projection and injection vectors denoted by $\langle 0 \rangle$ $\langle 1 \rangle$ etc. and $|0|$ $|1|$ etc., respectively.

| <u>Examples</u> | <u>Signature</u> | <u>Description</u> |
|------------------------|---------------------------|------------------------|
| $\langle 0 \rangle$ | $(A,B) \rightarrow A$ | projection vector |
| $\langle 1 \rangle$ | $(A,B) \rightarrow B$ | projection vector |
| $ 0 $ | $A \rightarrow (A;B)$ | injection vector |
| $ 1 $ | $B \rightarrow (A;B)$ | injection vector |
| $ 1 $ $ 2 $ $ 3 $ etc. | 1->number | element of enumeration |
| $\langle a \rangle$ | $(a:A,b:B) \rightarrow A$ | labelled projection |
| $ a $ | $A \rightarrow (a:A;b:B)$ | labelled injection |

A Short Summary of the Evaluate Modelling Language

Projections and injections are used with composition to form selection and restriction operators. See below.

10) Vector expressions

New vectors can be formed from known vectors by writing vector expressions. Each vector expression gives rise to domain expressions in the signature of the resulting vector.

11) Composition

For any domains A, B, C and vectors $f:A \rightarrow B$ $g:B \rightarrow C$ the expression

$g \circ f$

(read g of f) denotes a vector with signature $A \rightarrow C$. Composition is associative, i.e. for any domain D and vector $h:C \rightarrow D$

$$h \circ (g \circ f) = (h \circ g) \circ f$$

Composition has left and right identities.

12) Right identity

For any domains A B and vector $f:A \rightarrow B$, the expression

$\text{sbj } f$

denotes the right composition identity with signature $A \rightarrow A$.

$$f \circ (\text{sbj } f) = f$$

13) Left identity

For any domains A B and vector $f:A \rightarrow B$, the expression

$\text{obj } f$

denotes the left composition identity with signature $B \rightarrow B$.

$$(\text{obj } f) \circ f = f$$

13) Pairing

For any domains A B C and vectors $f:A \rightarrow B$ $g:A \rightarrow C$ the expression

$\langle f, g \rangle$

denotes a vector with signature $A \rightarrow (B, C)$.

A Short Summary of the Evaluate Modelling Language

14) Tupleing

More generally, for domains A B_1 B_2 B_3 etc and vectors $f_1:A \rightarrow B_1$
 $f_2:A \rightarrow B_2$ $f_3:A \rightarrow B_3$...

f_1, f_2, f_3, \dots

denotes a vector with signature $A \rightarrow (B_1, B_2, B_3, \dots)$

15) Selection

Composition with a project vector is called selection. For a vector
 $x:A \rightarrow (B, C)$ the composition

$\langle 0 \rangle x$

denotes a vector with signature $A \rightarrow B$. $\langle 0 \rangle$ denotes the projection
vector whose signature depends on the context. In this case its
signature is $\langle 0 \rangle:(B, C) \rightarrow B$.

Similarly

$\langle 1 \rangle x$

denotes a vector with signature $A \rightarrow C$, i.e. the composition with
projection $\langle 1 \rangle:(B, C) \rightarrow C$.

16) Empty projection

Composition with the empty projection

$\langle \rangle x$

denotes the unique vector $A \rightarrow 1$.

Pairing and selection are related by

$$\begin{aligned}\langle 0 \rangle(f_0, f_1) &= f_0 \\ \langle 1 \rangle(f_0, f_1) &= f_1\end{aligned}$$

These equations extend to tuples.

17) General pairing (type coercion)

For any domains A , B , C , and D where A and B represent different
domains and vectors $f:A \rightarrow C$ and $g:B \rightarrow D$, the expression

f, g

denotes a vector with signature $(A, B) \rightarrow (C, D)$ defined by

A Short Summary of the Evaluate Modelling Language

(f id<0>),(g id<1>)

where id = obj((sbj f)||,(sbj g)||).

18) Labelled pairing

For domains A, B, C and vectors $f:A \rightarrow B$ and $g:A \rightarrow C$ the expression

$a:f,b:g$

denotes the vector with signature $A \rightarrow (a:B,b:C)$

Similarly, for domains A, B, C, and D with A not the same as B and vectors $f:A \rightarrow C$ and $g:B \rightarrow D$

$a:f,b:g$

denotes a vector with signature $(a:A,b:B) \rightarrow (a:C,b:D)$ defined as above.

19) Labelled selection

$\langle a \rangle$ denotes a projection vector from a labelled pairing. Thus,

$\langle a \rangle(a:f,b:g)=f$

$\langle b \rangle(a:f,b:g)=g$

In programming languages with record structures, for example in Pascal,

```
var f: record a:A; b:B; c:C; end;
```

labelled selection corresponds to the 'dot' notation

$f.a$

20) Glueing

Glueing and restriction are analogous to projection and selection. For domains A, B, C, D with C and D different domains and vectors $f:A \rightarrow C$ $g:B \rightarrow C$ and $h:B \rightarrow D$ we have following glueing expressions

| <u>Expression</u> | <u>Signature</u> | <u>Definition</u> |
|-------------------|-----------------------------------|---|
| $f;g$ | $(A;B) \rightarrow C$ | |
| $g_1;g_2;g_3$ | $(B_1;B_2;B_3) \rightarrow C$ | |
| $a:f;b:g$ | $(a:A;b:B) \rightarrow C$ | |
| $f;h$ | $(A;B) \rightarrow (C;D)$ | $(\langle 0 \rangle \text{id } g);(\langle 1 \rangle \text{id } e)$ |
| $a:f;h:e$ | $(a:A;b:B) \rightarrow (a:C;b:D)$ | |

where id = sbj($\langle \rangle$ (obj g); $\langle \rangle$ (obj e))

A Short Summary of the Evaluate Modelling Language

21) Restriction

For domains A, B, C and vector $z:(A;B)\rightarrow C$, we have the following restriction expressions

| <u>Expression</u> | <u>Signature</u> | <u>Definition</u> |
|-------------------|------------------|--|
| $z 0 $ | $A\rightarrow C$ | composition with injection $A\rightarrow(A;B)$ |
| $z 1 $ | $B\rightarrow C$ | composition with injection $B\rightarrow(A;B)$ |
| $z $ | $0\rightarrow C$ | empty injection |

Glueing and restriction are related by

$$\begin{aligned}(g_0;g_1)|0| &= g_0 \\ (g_0;g_1)|1| &= g_1\end{aligned}$$

or with labels

$$\begin{aligned}(a:g_0;b:g_1 \dots)|a| &= g_0 \\ \text{etc.}\end{aligned}$$

22) Nesting

For domains A B C and vector $x:(A,B)\rightarrow C$ the expression

$$x\langle 0 \rangle$$

denotes a vector with signature $A\rightarrow(B\rightarrow C)$ i.e. a vector whose elements are themselves vectors (elements of a vector space).

Similarly, the expression

$$x\langle 1 \rangle$$

denotes a vector with signature $B\rightarrow(A\rightarrow C)$.

23) Flattening

For any vector $w:A\rightarrow(B\rightarrow C)$

$$\text{flat } w$$

denotes the vector with signature $(A,B)\rightarrow C$.

Nesting and flattening are related by

$$\begin{aligned}(\text{flat } w)\langle 0 \rangle &= w \\ \text{flat}(x\langle 0 \rangle) &= x\end{aligned}$$

A Short Summary of the Evaluate Modelling Language

24) Naming

For any vector $f:A \rightarrow B$, the expression

$$f \langle \rangle$$

denotes a vector with signature $1 \rightarrow (A \rightarrow B)$ which names the vector as an element of vector space.

25) Transpose

Thinking of the vector $x:(A,B) \rightarrow C$ as a matrix, we may form the transpose of x by composition with paired projections. The expression

$$x \langle 1, 0 \rangle$$

denotes the vector with signature $(B,A) \rightarrow C$.

25.1) Interchange

Given a vector whose object is a glueing, $x:A \rightarrow (B;C)$ we may interchange the order of the components of the object by composition with glued injections. The expression

$$|1, 0| x$$

denotes the vector with signature $A \rightarrow (C;B)$

26) Equalizer

For any domains A and B and vectors $f:A \rightarrow B$ and $g:A \rightarrow B$ the expression

$$f = g$$

denotes a vector with signature $n \rightarrow A$ which points out the largest subset of A over which f and g agree.

A Short Summary of the Evaluate Modelling Language

27) Range

For any domains A B and vector $f:A \rightarrow B$, the expression

$\{f\}$

denotes a boolean vector with signature $B \rightarrow 2$ such that for each element of B

$y:1 \rightarrow B$

which occurs in the range of f, i.e. for which there exists a

$x:1 \rightarrow A$

with $f x = y$ then

$\{f\} y = |1|$

28) Equality

For any domain A there is an operator called equality with signature

$eql:(A,A) \rightarrow 2$

For any domains A B and vectors $f:A \rightarrow B$ $g:A \rightarrow B$, equalizer, equality and range are related by

$eql(f,g) = \{f=g\}$

29) Boolean vectors

The enumeration domain 2 has two elements. These elements also serve as truth values.

| <u>Element</u> | <u>Signature</u> | <u>Description</u> |
|----------------|-------------------|--------------------|
| 0 | $1 \rightarrow 2$ | false |
| 1 | $1 \rightarrow 2$ | true |

Vectors of the form $x:A \rightarrow 2$ where A stands for any domain expression, are called boolean vectors. For any boolean vector $x:A \rightarrow 2$, the expression

$true x$

denotes a vector with signature $n \rightarrow A$ where n is an enumeration domain. True is related to range by

$\{true x\} = x$

A Short Summary of the Evaluate Modelling Language

True can be defined in terms of equalizer as

$$x = |1|$$

30) Co-equalizer

For any vectors $f:A \rightarrow B$ and $g:A \rightarrow B$, the expression

$$\text{coe}(f,g)$$

denotes a vector with signature $B \rightarrow n$. $\text{coe}(f,g)$ represents the finest partition of B which makes f and g agree.

31) Title sets

| <u>Name</u> | <u>Expression</u> | <u>Signature</u> | <u>Definition</u> |
|----------------|-------------------|-----------------------|------------------------------|
| subject titles | $\$f$ | $\{f\} \rightarrow A$ | subject titleset constructor |
| object titles | $@f$ | $A \rightarrow \{f\}$ | object titleset constructor |

These vectors are used together with composition to associate title sets with untitled vectors.

32) Groupings

| <u>Name</u> | <u>Expression</u> | <u>Signature</u> | <u>Definition</u> |
|------------------|-------------------|-----------------------|---------------------------|
| subject grouping | $f\$$ | $\{f\} \rightarrow A$ | subject group constructor |
| object grouping | $f@$ | $A \rightarrow \{f\}$ | object group constructor |

These vectors are used together with composition to associate groupings with untitled vectors.

33) Real Arithmetic

For domain A and vectors $m:A \rightarrow \text{REAL}$ and $n:A \rightarrow \text{REAL}$, we have the following element-wise arithmetic expressions

| <u>Name</u> | <u>Infix</u> | <u>Expression</u> | <u>Signature</u> |
|----------------|--------------|-------------------|-----------------------------|
| addition | $m+n$ | $\text{add}(m,n)$ | $A \rightarrow \text{REAL}$ |
| multiplication | $m*n$ | $\text{mul}(m,n)$ | $A \rightarrow \text{REAL}$ |
| subtraction | $m-n$ | $\text{sub}(m,n)$ | $A \rightarrow \text{REAL}$ |
| division | m/n | $\text{div}(m,n)$ | $A \rightarrow \text{REAL}$ |

33.1) Real Vector Space Arithmetic

The above element-wise expressions are extended to vectors whose objects are real vector spaces. A real vector space is a vector space of the form $(A \rightarrow \text{REAL})$ for any domain A . For any domains $A B C$ with B and C different and vectors $m:A \rightarrow \text{REAL}$ $n:A \rightarrow \text{REAL}$ $p:A \rightarrow (B \rightarrow \text{REAL})$ $q:A \rightarrow (B \rightarrow \text{REAL})$ $r:A \rightarrow (C \rightarrow \text{REAL})$ we have the following cases:

A Short Summary of the Evaluate Modelling Language

| Expression | Signature | Description |
|------------|---|-------------------------------|
| $m+p$ | $A \rightarrow (B \rightarrow \text{REAL})$ | Scalar by vector |
| $p+q$ | $A \rightarrow (B \rightarrow \text{REAL})$ | Element-wise vector by vector |
| $q+r$ | $A \rightarrow ((B,C) \rightarrow \text{REAL})$ | Outer vector by vector |

34) Summation, Aggregation and Linear Interpolation

For domains A B and vectors $x:A \rightarrow (B \rightarrow \text{REAL})$ $f:A \rightarrow B$ $m:A \rightarrow \text{REAL}$
 $n:A \rightarrow \text{REAL}$ $ts:\{m\} \rightarrow \text{REAL}$

| Name | Expression | Signature | Definition |
|----------------|------------|-----------------------------|--|
| summation | sum x | $A \rightarrow \text{REAL}$ | sum over domain B |
| aggregation | agg(f,m) | $B \rightarrow \text{REAL}$ | sum m(i) for f(i)=j, i in A, j in B |
| linear interp. | line(ts;n) | $A \rightarrow \text{REAL}$ | step-wise linear function line(ts;_): $\text{REAL} \rightarrow \text{REAL}$ |

35) New Operators

Evaluate is easily extended since any name which is not defined as a variable is treated as an operator. Thus if XXX is not defined, then the use of XXX in an expression. e.g.

XXX (...)

is translated as an operator. XXX is expected to be the name of a low-level filter.

36) Operator Expressions

When operators appear at the lowest level in an expression, rather than vectors, the result is called an operator expression. For example, the expression

(sbj,obj)

denotes the operation evaluating the subject and object of a vector then pairing the result. A special operator (underscore) called the null operator is available to form operator expressions such as

(+)

This operator can be applied to a vector whose object is REAL. The result is a vector whose elements are twice the original value.

A Short Summary of the Evaluate Modelling Language

37) Using Evaluate

To enter Eunice from VMS type:

```
$ csh
```

Programs are in directory /u/page/bin. This should be added to your PATH.

Three sub-directories are expected in the working directory in which Evaluate is run:

```
inp    contains input vector values
out    contains output vector values
tmp    contains temporary vector values
scn    contains views
```

Evaluate is initiated by the command

```
eva [-l] [viewname]
```

-l option causes low-level shell code to be output to stdout instead of being executed. This allows ev to be used as a "compiler" for the low-level language. If viewname is included, variable definitions and values are loaded from the specified file in sub-directory scn.

38) Evaluate commands:

| | |
|--------------------|---|
| exit | Exit Evaluate |
| clear [varname] | Deletes all variables or a specified variable definition and value |
| load viewname | Retrieve variable definitions and values from a file |
| save viewname | Save variable definitions and values on a file |
| reset [varname] | Delete all or a specified temporary variable value(s) |
| list [varname] | List all variable definitions and values or a cross-reference of a specific variable. |
| varname:filename | Assign a value to a variable |
| varname=expression | Define a variable |
| edit varname | Full screen edit of value of variable |
| expression | Print the value of the expression |

expression stands for any vector or operator expression defined above.

39) Variable names

Variable names must begin with a letter. Upper and lower case letters are treated as distinct. The list of variables with their definitions and values is maintained in alphabetical order by variable name.

A Short Summary of the Evaluate Modelling Language

40) Values

Values of variables are stored as files. The `save` command, in addition to saving the definitions of all variables as a view file, causes the temporary values of variables to be saved as permanent files in either the `inp` or `out` sub-directories. `inp` is used if the variable has no definition. `out` is used if it has both a definition and a value. The permanent file name is formed by appending a sequential numeric extension to the variable name.

41) File names

Note that paths part of file names in Evaluate use the `\` delimiter, not `/` as in Eunice.

42) Interface with TERF

To retrieve a vector from the TERF inventory:

While outside of evaluate (in the shell) issue the command:

```
getinv matrixname
```

A file called `matrixname` and any associated titlesets will be written to the `inp` sub-directory in your working directory.

When in Evaluate assign `matrixname` as the value of a variable, e.g.

```
matrix:matrixname
```

Now `matrix` may be used in expressions.
